GUIDELINE

Endpoints used in relative effectiveness assessment of pharmaceuticals

SAFETY

Final version
February 2013
The primary objective of EUnetHTA JA1 WP5 methodology guidelines is to focus on methodological challenges that are encountered by HTA assessors while performing a rapid relative effectiveness assessment of pharmaceuticals.

This guideline “Endpoints used for REA of pharmaceuticals - Safety” has been elaborated by experts from AIFA, reviewed and validated by HAS and all members of WP5 of the EUnetHTA network; the whole process was coordinated by HAS. As such the guideline represents a consolidated view of non-binding recommendations of EUnetHTA network members and in no case an official opinion of the participating institutions or individuals.

Summary and recommendations

Summary

This guideline aims at providing a framework for the evaluation of relative safety performed by HTA assessors in the context of Relative Effectiveness Assessment (REA) of pharmaceuticals. When performing relative safety assessment the safety profile of the pharmaceutical is assessed in comparison to the comparator(s) of the same or different therapeutic class and to the safety profile of non-pharmaceutical alternatives (when available).

It is important to carry out balanced assessments of the interventions, taking into account both beneficial and adverse effects, in order to support clinicians, policy makers and patients in making informed decisions. For this reason beneficial and adverse reactions/effects should be assessed with similar methodological rigour and accuracy. Although the importance of a balanced assessment is well recognised the assessment of adverse reactions/effects is still more troublesome than the assessment of benefits. In this guideline some important methodological issues concerning relative safety assessment have been addressed and recommendations were given.

Consistent and precise terminology should be used and for this purpose the MedDRA should be used for describing adverse reactions/effects.

When conducting a rapid assessment, just after the marketing authorisation of a medicine, European Public Assessment Report (EPAR), Summary of Product Characteristics (SPC), Risk Management Plan (RMP) (when available), manufacturer’s dossier and published and unpublished randomised clinical trials are generally used as primary sources of information. It is important to assess, apart from risk of bias of studies, also the quality of data on adverse effects, taking into account how adverse effects data are collected and reported to decide on their inclusion and interpretation. Main characteristics of selected studies and their limitations should be described and reported preferably in tabular form.

Results from individual studies should be reported both for the pharmaceutical and comparator(s), using summary tables for the different study designs.

Finally, the assessment of relative safety should be performed between the pharmaceutical and its comparator(s) with special regard to the most frequent, serious and severe adverse reactions. This assessment together with the assessment of comparative benefits will contribute to establish a balanced assessment of the relative effectiveness of the pharmaceutical and to decide upon the possible consequences on coverage decision.

In the discussion of results limitations and external validity of results should be investigated and discussed, considering all factors (e.g. patient characteristics, co-morbidities, type and severity of disease) which may contribute to the occurrence of adverse reactions.

Recommendations

<table>
<thead>
<tr>
<th>Recommendation</th>
<th>The recommendation is based on the following elements</th>
</tr>
</thead>
<tbody>
<tr>
<td>Recommendation 1</td>
<td>2.1. Objectives of the HTA assessors</td>
</tr>
</tbody>
</table>

In relative safety assessment of pharmaceuticals main objectives of HTA assessors are summarised as follows:
- To identify the adverse reactions
- To quantify the adverse reactions in terms of frequency categories, incidence, severity and seriousness
- To compare the safety profile of the pharmaceutical with its comparator(s)/best standard of care.
Recommendation 2
HTA assessors may focus their investigation on the following areas:
- The most frequent adverse reactions.
- The “important identified” and “potential” risks associated with use of the product, according to the RMP. These should include only the important identified and potential adverse events/reactions, important identified and potential interactions with other medicinal products, foods and other substances, and the important pharmacological class effects.

Recommendation 3
The HTA assessors should use consistent and precise terminology to avoid misleading results. They should use the MedDRA Dictionary for describing adverse reactions.

Recommendation 4
Main sources of information of HTA assessors are:
- EPAR, SPC and RMP (when available)
- Published and unpublished (where acceptable under the specific HTA system guidelines) randomised clinical trials
- Manufacturer dossier
- Unpublished full study reports (where acceptable under the specific HTA system guidelines)
- Observational studies

Recommendation 5
It is necessary to evaluate both the risk of bias of sources of information and the quality of data on adverse reactions. Methods used to assess the risk of bias should be clearly described and results should be reported. It should be clearly explained how the information on risk of bias will be used in the synthesis of data.

To assess the data on adverse reactions, how the adverse effects were collected and reported should be evaluated.

Useful questions to assess how the adverse reactions are collected:
- Were definitions given of reported adverse effects?
- How were adverse effects data collected: prospective/routine monitoring, spontaneous reporting, patient checklist/questionnaire/diary; systematic survey of patients?

Useful questions to assess how the adverse effects are reported:
- Were any patients excluded from the adverse effects analysis?
- Did the report give numerical data by intervention group?
- Which categories of adverse effects did the investigators report?
- Did investigators report on all important or serious adverse effects, and how were these defined?
- Were methods used for monitoring adverse effects reported?
- Was an independent data safety monitoring board established?

**Recommendation 6**
Characteristics of selected studies should be summarised in a table. Useful information on studies characteristics are the following:
- methods (study design, follow-up period);
- participants for both arms (setting, age, sex and country/geographic area),
- intervention and comparators (for pharmaceuticals: the name, dose, frequency, way of administration and duration);
- outcomes;
- methods to collect adverse effects.

Different tables should be elaborated for RCTs and observational studies.

**Recommendation 7**
Results from individual studies should be presented by group in tabular form, using the following measures:
- Number of participants in both study arms
- Number of patients excluded from the analysis dataset
- Patient-years of exposure
- Number of participants with the event
- Number of events
- Absolute risk; incidence rate (95% CI)
- Relative risk (95% CI)
- Quality of evidence

Different tables should be elaborated for RCTs and observational studies.

Adverse effects should be grouped according to the System Organ Class (SOC).
Adverse effects which are common and serious should be reported separately.
If possible, adverse effects should also be provided by severity grade.
When adverse effects are collected from different study designs and when the degree of heterogeneity is high the data cannot all be pooled together using standard meta-analysis principles.
Therefore in these circumstances adverse effects data is best summarised in a qualitative or descriptive manner.

**Recommendation 8**
The safety profile of the pharmaceutical is described in comparison to the comparator(s), with special regard to the most frequent, serious and severe adverse reactions.
A table is preferable for the comparison of the safety profile of the new pharmaceutical and the comparator(s).
HTA assessors should describe if there is a clinically significant difference in adverse reactions between products.
In the discussion of results limitations and external validity should be investigated and discussed, considering all factors (e.g.}

**2.5.1 Description of included sources of information**

**2.5.2 Quantification of adverse effects in terms of frequency, incidence, severity and seriousness**

**2.5.3 The comparison of the safety profile of the pharmaceutical to the comparator(s)**
patient characteristics, co-morbidities, type and severity of disease) which may contribute to the occurrence of adverse reactions.

EUnetHTA – European network for Health Technology Assessment
1. Introduction

1.1. Definitions

**Adverse effects and adverse reaction**

The two terms refer to the same phenomenon, but an adverse effect is seen from the point of view of the pharmaceutical, whereas an adverse reaction is seen from the point of view of the patient. The pharmaceutical causes an effect, whereas the patient has a reaction.

**Adverse event**

Any untoward medical occurrence in a patient administered a medicinal product and which does not necessarily have to have a causal relationship with this treatment.

An adverse event (AE) can therefore be any unfavourable and unintended sign (for example, including an abnormal laboratory finding,), symptom, or disease temporally associated with the use of a medicinal product, whether or not considered related to the medicinal product.

ICH Harmonised Tripartite Guideline. Post approval safety data management: definitions and standards for expedited reporting (ICH E2D)

**Adverse reaction/adverse drug reaction**

Noxious and unintended effects resulting not only from the authorised use of a medicinal product at normal doses, but also from medication errors and uses outside the terms of the marketing authorisation, including the misuse and abuse of the medicinal product. The suspicion of an adverse drug reaction, meaning that there is at least a reasonable possibility of there being a causal relationship between a medicinal product and an adverse event should, be sufficient reason for reporting.

**Adverse reaction (Serious)**

An adverse reaction which results in death, is life-threatening, requires in-patient hospitalisation or prolongation of existing hospitalisation, results in persistent or significant disability or incapacity, or is a congenital anomaly/birth defect, and is a medically important event or reaction.

For the terms "serious" and "severe," which are not synonymous, the following note of clarification is provided: The term "severe" is often used to describe the intensity (severity) of a specific event (as in mild, moderate, or severe myocardial infarction); the event itself, however, may be of relatively minor medical significance (such as severe headache). This is not the same as "serious," which is based on patient/event outcome or action criteria usually associated with events that pose a threat to a patient's life or functioning. Seriousness (not severity) serves as a guide for defining regulatory reporting obligations.

ICH Harmonised Tripartite Guideline. Post approval safety data management: definitions and standards for expedited reporting (ICH E2D)

**Adverse reaction (Severity Grade)**

**Grade 1**

Mild; asymptomatic or mild symptoms; clinical or diagnostic observations only; intervention not indicated.

**Grade 2**

Moderate; minimal, local or non-invasive intervention indicated; limiting age-appropriate instrumental Activities of Daily Living

**Grade 3**
Severe or medically significant but not immediately life-threatening; hospitalization or prolongation of hospitalization indicated; disabling; limiting self care Activities of Daily Living.

**Grade 4**
Life-threatening consequences; urgent intervention indicated.

**Grade 5**
Death related to AE.

**Adverse reaction (Unexpected)**
An adverse reaction, the nature or severity of which is not consistent with the applicable product information.

Source: ICH Harmonised Tripartite Guideline. Clinical Safety Data Management: Definitions and Standard for Expedited Reporting E2A

An ADR whose nature, severity, specificity, or outcome is not consistent with the term or description used in the local/regional product labelling (e.g. Package Insert or Summary of Product Characteristics) should be considered unexpected. When a Marketing Authorisation Holder is uncertain whether an ADR is expected or unexpected, the ADR should be treated as unexpected.

Source: ICH Harmonised Tripartite Guideline. Post approval safety data management: definitions and standards for expedited reporting (ICH E2D)

**Benefit - Risk Balance**
In the regulatory context: an evaluation of the positive therapeutic effects of the medicinal product in relation to its risks (any risk relating to the quality, safety or efficacy of the medicinal product as regards patients' health or public health and any risk of undesirable effects on the environment).

**Case by Case Causality assessment**
The evaluation of the likelihood that a medicine was the causative agent of an observed adverse reaction. Causality assessment is usually made according established algorithms.

**Classification of causality**

- **Certain**
- A Clinical event, including a laboratory test abnormality, that occurs in a plausible time relation to drug administration and which cannot be explained by concurrent disease or other drugs or chemicals
- The response to withdrawal of the drug (dechallenge) should be clinically plausible
- The event must be definitive pharmacologically or phenomenologically, using a satisfactory rechallenge procedure if necessary

- **Probable/likely**
- A clinical event, including a laboratory test abnormality, with a reasonable time relation to administration of the drug, unlikely to be attributed to concurrent disease or other drugs or chemicals, and which follows a clinically reasonable response on withdrawal (dechallenge)
- Rechallenge information is not required to fulfil this definition

- **Possible**
- A clinical event, including a laboratory test abnormality, with a reasonable time relation to administration of the drug, but which could also be explained by concurrent disease or other drugs or chemicals
- Information on drug withdrawal may be lacking or unclear

- **Unlikely**
  - A clinical event, including a laboratory test abnormality, with a temporal relation to administration of the drug, which makes a causal relation improbable, and in which other drugs, chemicals, or underlying disease provide plausible explanations

- **Conditional/unclassified**
  - A clinical event, including a laboratory test abnormality, reported as an adverse reaction, about which more data are essential for a proper assessment or the additional data are being examined

- **Unassessable/unclassifiable**
  - A report suggesting an adverse reaction that cannot be judged, because information is insufficient or contradictory and cannot be supplemented or verified

**Causal relationship**
A relationship between one phenomenon or event (A) and another (B) in which A precedes and causes B. Source: WHO. Glossary of terms used in Pharmacovigilance

**Harms**
The totality of possible adverse consequences of an intervention or therapy; they are the direct opposite of benefits, against which they must be compared.

The nature and extent of actual damage that could be caused by a drug.
Source: WHO. Glossary of terms used in Pharmacovigilance

**Pharmacovigilance**
The science and activities relating to the detection, assessment, understanding and prevention of adverse effects or any other drug related problem.

**Risk**
The probability that an event will occur, e.g., that an individual will become ill or die within a stated period of time or by a certain age.
Also a nontechnical term encompassing a variety of measures of the probability of a (generally) unfavourable outcome.

**Safety**
Substantive evidence of an absence of harm. The term is often misused when there is simply absence of evidence of harm.
Side effect
Unintended drug effects. The term, however, does not necessarily imply harm, as some side effects may be beneficial. Furthermore, it tends to understate the importance of harms because “side” may be perceived as denoting secondary importance.

It is recommended that this term no longer be used and particularly should not be regarded as synonymous with adverse event or adverse reaction.
Source: ICH Harmonised Tripartite Guideline. Clinical Safety Data Management: Definitions and Standard for Expedited Reporting E2A

Tolerability
A term that usually refers to medically less important (i.e. without serious or permanent sequelae) but unpleasant adverse effects of drugs. These include symptoms such as dry mouth, tiredness, etc, that can affect a person's quality of life and willingness to continue the treatment. As these adverse effects usually develop early and are relatively frequent, RCTs may yield reliable data on their incidence.

Toxicity
Describes drug-related harms. The term may be most appropriate for laboratory-determined measurements, although it is also used in relation to clinical events. Abnormal laboratory values may be described as laboratory-determined toxicity. The disadvantage of the term “toxicity” is that it implies causality. If authors cannot prove causality, the terms “abnormal laboratory measurements” or “laboratory abnormalities” are more appropriate to use.

1.2. Context and problem statement
The importance of assessing both benefits and adverse reactions with similar rigour in order to provide balanced assessments of alternative interventions is well recognised. Nevertheless, assessing adverse effects may be difficult because of the greater prominence given to the beneficial effects of therapies and the ongoing methodological issues with assessment of adverse effects.

In the context of safety two different evaluations are performed:
- The benefit-risk assessment carried out by regulatory authorities, during the pre-approval phase to grant marketing authorisation and continuously during the post-approval phase taking into account new risks or changes in known risks.
- The relative safety assessment of a medicine or a class of medicines, conducted by HTA assessors. In this case the safety profile of a pharmaceutical is compared to the safety profile of the comparator(s) belonging to the same or different therapeutic class and to the safety profile of non pharmaceutical alternatives (when available). In some cases it could be also necessary to consider how both the intervention and the comparator are administered and if different procedures may contribute to the occurrence of adverse reactions.
1.3. **Scope/Objective(s) of the guideline**

This guideline focuses on the relative safety assessment performed by the HTA assessors when conducting Relative Effectiveness Assessment (REA) of pharmaceuticals and deals with the following methodological issues:

- objectives of HTA assessors
- terminology
- identification of adverse reactions: sources of information
- evaluation of sources of information
- synthesis and reporting of results compared to other interventions

These issues are addressed and discussed in the main chapters of the document.

1.4. **Related EUnetHTA documents**

This guideline should be read in conjunction with the following documents:

- EUnetHTA guideline on Endpoints used in REA of pharmaceuticals: Composite endpoints
- EUnetHTA guideline on levels of evidence: applicability of evidence in the context of relative effectiveness assessment of pharmaceuticals
- EUnetHTA guideline on levels of evidence: internal validity (of randomized controlled trials)
- EUnetHTA guideline on comparators and comparisons: direct and indirect comparisons
2. Analysis and synthesis of literature

2.1 Objectives of the HTA assessors

In relative safety assessment of pharmaceuticals the main objectives of HTA assessors should be the following:

- To identify the adverse effects
- To quantify the adverse effects in terms of frequency, incidence, severity and seriousness
- To compare the safety profile of the pharmaceutical with its comparator(s)

Finally, in a context of Relative Effectiveness Assessment, HTA assessors will discuss in a balanced way the adverse effects and benefits related to the technology in comparison with alternatives.

Within the REA, the relative safety assessment can contribute to coverage decisions; because of the safety profile of a medicine in comparison with alternatives payers can decide:

- to limit the coverage to specific population subgroups and to specific therapeutic indications
- to partially reimburse or to not reimburse the pharmaceutical.

In order to carry out analyses in a systematic, manageable and useful way HTA assessors may focus their investigation on the following areas:

- the most frequent adverse reactions
- The important identified and potential risks associated with use of the product, according to the RMP. These should include only the important identified and potential adverse events/reactions, important identified and potential interactions with other medicinal products, foods and other substances, and the important pharmacological class effects.

2.2 Terminology

It is important that the HTA assessors use consistent and precise terminology to avoid confusion and misleading conclusions. For this purpose the Medical Dictionary for Regulatory Activities (MedDRA), developed by the International Conference on Harmonisation, could be a useful instrument. MedDRA includes medical signs, symptoms, syndromes and diagnoses as well as social conditions, surgical and medical procedures and laboratory and clinical investigations. It comprises five levels: lowest level terms (LLTs); preferred terms (PTs); high level terms (HLTs); high level group terms (HLGTs) and it is organised in 26 system organ classes (SOCs). It is important to note that due to the multiaxial structure of MedDRA, it may be necessary to combine several PTs in order to represent and to analyse one overlying medical concept (e.g. bleeding). In most cases it is not sufficient to rely upon one single PT. Standardised MedDRA Queries (SMQs), which are provided with the regular terminology updates, are preferred, especially when analysing medical conditions involving PTs across several SOCs.

MedDRA does not include a severity ranking. The use of MedDRA for recording and reporting adverse effects/reactions data on marketed medicines is mandatory in the European Union. MedDRA is available free of charge to regulatory authorities and to certain non-profit-making organisations and on payment of an annual subscription to other users. Since MedDRA contains neither severity descriptors nor descriptors of seriousness or intensity it may be useful to consider these characteristics of adverse effects in line with ICH E2D. The definitions given in this guideline (chapter 1.1) provide an adequate and comprehensive foundation for the analysis of adverse effects regarding characteristics not covered by MedDRA.

Besides MedDRA-coded adverse events it may be useful to also analyse endpoints measuring harms not based on this terminology. These concern explicitly pre-planned endpoints which are recorded according to pre-planned definitions (e.g. different evaluations of bleeding events: major
bleeding, minor bleeding etc). For observational studies in claims databases and electronic health records, other terminology may be used for AE assessment (ICD-9, ICD-10, READ).

### 2.3 Identification of adverse reactions: sources of information

A broad range of evidence sources may be considered to identify adverse effects relevant for the assessment. These sources may include regulatory sources (e.g. EPAR, SPC and RMP), manufacturer dossier, randomised clinical trials, observational studies, country registries and case reports. Various sources can bring different and complementary information; randomised clinical trials may inform on common risks, whereas other data sources, although at higher risk of bias, (e.g. observational studies, country registries and case reports) can give insight on less frequent risks, long-term risks, and risks in populations not being part of randomised clinical trials. Singh et al used RCTs and observational studies to assess the risk of heart of failure associated to thiazolidinediones and collected complementary information from case reports on specific characteristics of adverse effects such as dose, time and susceptibility factors.\(^{46}\)

In practice, for the identification of adverse effects in the first appraisal, the most important sources of data that are used by HTA assessors are the EPAR, SPC, RMP (when available), manufacturer dossier and randomised clinical trials reports and/or publications. When possible, adverse effects relevant for the assessment should be identified in advance and should be listed in the protocol of the HTA report.

#### 2.3.1 Regulatory sources

The regulatory authorities’ documentation (mainly EPAR and SPC) elaborated during approval phase is an important source of information and the most commonly available, especially when conducting rapid assessment. Moreover regulatory agencies provide important data in the post approval phase as well.

Data from different regulatory authorities, when available, should be used and compared for two main reasons:

- The safety assessments from different regulatory authorities may vary
- The technology may have different regulatory status across different jurisdictions: it could be in the approval phase in a jurisdiction and may have been marketed in a different jurisdiction.

**Data at approval phase**

At approval phase regulatory authorities synthesise the available data in specific documents.

At European level (EMA):

- The European Public Assessment Report (EPAR) and the Summary of Product Characteristics (SPC) provide a useful summary of adverse effects of medicines\(^{11}\) and may be useful to obtain data in order to evaluate adverse effects and to compare them between different products. They represent the main evidence for the HTA assessors.
- The Risk Management Plan (RMP), which is presented by applicants and/or marketing authorisation holders to describe the pharmacovigilance and risk minimisation activities summarises the important identified and potential risks of a medicinal product and important missing information on unidentified risks. A summary of the RMP will be publicly available according to the new European legislation. Assessors should also determine whether risk minimization activities (RMM) are required.

- HTA Assessors should verify if post-authorisation safety studies (PASS) were required. Post-authorisation safety studies (PASS) can be required by regulatory authorities either as
a commitment at the time of authorisation or in the post-authorisation phase to further assess a signal. 12

At US level (FDA):
- Medical review
- Summary review
- Risk evaluation and mitigation strategy (REMS)
- Statistical review

At Australian level (TGA)
- Australian Public Assessment Report (AusPAR)

At Canadian level (Health Canada)
- Product Monograph

Data at post approval phase
After the marketing authorisation the safety profile is continuously monitored by pharmacovigilance systems of regulatory agencies. Spontaneous reports of suspected adverse drug reactions provide important early signals of safety concerns and include:

At European level:
Eudravigilance database, which collects reports received from EU regulatory agencies and from pharmaceutical companies. Data from EudraVigilance are published in the European database of suspected adverse drug reaction reports.

The periodic safety update report for marketed pharmaceuticals (PSUR) provides a critical evaluation of the benefit-risk balance of a medicinal product, in consideration of new or changing post-authorisation information and analyses all adverse reactions reported in the period since the last PSUR. 13 According to the new legislation the following documents shall be made publicly available by means of the European medicines web-portal:
- List of EU reference dates and frequency of submission of PSURs, final assessment conclusions of the adopted assessment reports;
- Pharmacovigilance Risk Assessment Committee (PRAC) recommendations including relevant annexes;
- Coordination Group for Mutual Recognition and Decentralized Procedures (CMDh) position including relevant annexes and where applicable, detailed explanation on scientific grounds for any differences with the PRAC recommendations;
- Committee for medicinal products for Human Use (CHMP) opinion including relevant annexes and where applicable, detailed explanation on scientific grounds for any differences with the PRAC recommendations;
- European Commission decision

The European Network of Centres for Pharmacoepidemiology and Pharmacovigilance (ENCePP) Database of Research Resources which is a public, fully searchable electronic index of the available EU research resources in the field of pharmacoepidemiology and pharmacovigilance. ENCePP is a collaborative scientific network coordinated by the European Medicines Agency and developed in collaboration with European experts in the fields of pharmacoepidemiology and pharmacovigilance. Its goal is to further strengthen the post-authorisation monitoring of medicinal products in Europe by facilitating the conduct of multi-centre, independent, post-authorisation studies focusing on safety and on benefit-risk, using available expertise and research experience across Europe.
At US level:

The Adverse Event Reporting System (AERS), which is the database which supports the FDA’s post-marketing safety surveillance program for all approved pharmaceuticals and therapeutic biological products. In MedWatch website FDA collects information about adverse reactions and data are publicly available.

At international level:

Vigibase Services, which is an international collection of spontaneous reports of suspected adverse reactions, from countries participating in WHO Program for International Drug Monitoring and is maintained by Uppsala Monitoring Centre. National and regional centres in all official and associated member countries have access to the data.

Early signal detection is the task of regulatory authorities and not really of HTA assessors. Unless confirmed by regulatory authorities, they should not contribute to a re-appraisal of a pharmaceutical by a HTA agency. There are other possible safety triggers for re-appraisal of a pharmaceutical: relevant serious adverse events observed post-authorisation that may change benefit/harm balance or published literature data indicating an increased risk (e.g. increased incidence of cancer). However, this information is assessed by regulatory authorities and, if they change the benefit-risk balance, appropriate measures are taken so that the benefit-risk balance remains positive (a restriction of conditions of use or the need of periodic diagnostic procedures, among others). At re-appraisal, identified safety concern of a pharmaceutical (e.g. incidence of hepatotoxicity) is compared to the same safety concern (incidence of hepatotoxicity) of a comparator. However the whole overall safety picture of both medicines has to be considered, in order to assess other advantages/disadvantages.

The European Commission has amended the current pharmacovigilance system and proposed new EU pharmacovigilance legislation (Regulation (EU) No 1235/2010 Directive 2010/84/EU) in order to continue to ensure greater patient safety. The new pharmacovigilance legislation will strengthen the current system for safety monitoring of medicines on the European market in order to obtain major robustness and transparency. A new scientific committee, the Pharmacovigilance Risk Assessment Committee (PRAC), was set up. The new pharmacovigilance legislation will cover all aspects of the risk management of the use of medicinal products for human use including the detention, assessment, communication relating to the risk of adverse reactions, taking into account the therapeutic effect of the medicinal product, the design and evaluation of post-authorisation safety studies and pharmacovigilance audit. It is useful to take into account the new rules laid down by the new pharmacovigilance legislation in consideration of the possible implications for the safety assessment in the field of Relative Effectiveness Assessment.

Where to find the information

- Medwatch: http://www.fda.gov/medwatch/index.html
- FDA summary review: http://www.fda.gov/Drugs/default.htm
2.3.2 Randomised Clinical Trials (RCTs)

From RCTs data on well-recognised, frequent, easily detectable adverse reactions are normally identified. Whether or not information on rare and long term effects that occur in clinical practice can be inferred from RCT, depends on the size, duration and other features of trials, but this also applies to all other types of studies. Clinical trials are usually powered to detect statistical significance of possible benefit(s) of a pharmaceutical and only secondly designed to study safety. As a result the evidence on adverse effects generated by RCTs may not be conclusive. Patients included in clinical trials may not reflect the features of populations who will undergo the treatment in clinical practice affecting the external validity of the trial. In fact RCTs may fail in identifying risks in populations not included in the trial and in identifying, depending on the design of the study, some categories of reactions such as reactions where young or old age is a risk factor, the effect of the medicine on other diseases, the effect on pregnancy, reactions related to female sex, reactions due to genetic variations in different ethnic groups, those associated with other uses not studied in the trial, withdrawal effects, and unfavourable changes in death rate because of low number of participants and short period of observation. Although head to head RCTs are the most direct evidence on comparative safety, placebo-controlled RCTs may be important to obtain information on absolute and relative risks and more precise estimates of adverse reactions. Studies sufficiently powered to assess (differences in) adverse effects, when possible, are important sources of information in the safety assessment. The HTA assessors should also attempt to include results of completed but not published RCTs and unpublished results of published trials. This kind of information may be collected searching abstracts presented during congresses and through the public assessment report performed by regulatory authorities.

2.3.3 Observational studies

RCTs are considered the best standard for evaluating benefits, but for safety assessment the use of additional sources of information could be necessary. In some cases, observational studies provide a wider number of participants observed for a longer period of time and may be more likely to capture rare and long term effects. Whether or not data from observational studies have higher degree of external validity than RCTs, depends on the specific question and the design of specific studies. Nevertheless, because of the lack of randomisation the observational studies are more subject to risk of bias, which are normally taken into account in the design itself or in the data analysis. There is debate concerning the capacity of the different study designs (randomised controlled trials and observational studies) to yield reliable quantitative estimate of adverse reactions. Papanikolaou et al. found that non randomised studies are often conservative in estimating absolute risks. These differences were largely due to inconsistencies in study populations. On the other hand a recent review presented no difference on average between estimates of adverse effects from meta-analyses of RCTs and of observational studies. Therefore it suggested evaluating a broad range of studies to obtain an exhaustive assessment of adverse reactions with wider generalisability.

Observational studies based on analyses of large administrative database are efficient in providing information on safety issues since they can be performed in shorter timeframes. They are probably more useful for evaluating serious adverse effects that are more reliably recorded than less serious adverse effects that may not generate a specific clinic visit or diagnostic code.

2.3.4 Case Reports

Case reports are useful to collect data on uncommon, unexpected or long-term adverse reactions not normally identified in clinical trials. One of the most important advantages of case reports is to contribute to signal generation which may then be confirmed by further studies.
A study showed that the 90% pharmaceuticals withdrawals from French market between 1998 and 2004 were supported by spontaneous case reports. This study was in accordance with Arnaiz et al which investigated reasons for withdrawals of pharmaceuticals in Spain between 1990 and 1999. However it should be pointed out that case reports present relevant limitations, being their role the generation of signals that need to be further confirmed. Limitations include the lack of important information, such as conclusive evidence on the estimate of the incidence. In addition, even though they may be published in scientific journals they are seldom subjected to confirmatory investigations.

### 2.3.5 How and where to find the information: search strategy

Because of poor indexing and inconsistent terminology the identification of studies reporting data on adverse reactions may be problematic.

There is no single approach of search strategy to collect evidence on adverse effects, but a combination of different approaches is required. Two main approaches can be followed: searching electronic database using index terms (such as MeSH in MEDLINE) and free text terms. The two approaches should be combined. A search through clinical trials registers (i.e. clinicaltrials.gov, EU clinical trials register, www.controlled-trials.com) to identify ongoing or completed but not published trials could provide additional information. In the EU, abstracts and summary results of post authorisation safety studies requested by regulatory authorities to marketing authorisation holders will be public according to new legislation. EVIDENT database could be searched for identifying requests/recommendations by agencies for additional evidence collection concerning safety.

### 2.4 Evaluation of sources of information

HTA assessors should adequately assess the risk of bias of studies and the quality of safety data to decide on the inclusion in the assessment and then on their interpretation.

#### 2.4.1 Regulatory sources

The documentation supporting authorisation usually includes clinical trials; therefore the quality issues relating RCTs described in the 2.4.2 paragraph can be applied also to the regulatory sources. Nevertheless the safety assessment from different regulatory authorities may vary, making a comparison useful. Moreover a technology may have a different regulatory status across jurisdictions; it could be in approval phase in a jurisdiction and may have been marketed in another jurisdiction and therefore different data may be available.

#### 2.4.2 Randomised clinical trials (RCTs)

It is recommended to evaluate both the risk of bias of individual studies and the quality of data on adverse effects. For the assessment of risk of bias several methods are available and they may be in the form of scales, checklist or individual components. A tool was developed by the Cochrane Collaboration. In any case methods used to assess the risk of bias should be clearly described and results should be reported, also in table format. Moreover it should be explained how the information on risk of bias will be used in the synthesis of data.

In assessing quality of data HTA assessors should evaluate two main aspects:
- how adverse effects were identified and collected and
- how they were reported.

HTA assessors should bear in mind that methods used to monitor or detect adverse effects greatly influence their reported frequency. As a result, studies using different methods of monitoring effects are difficult to be compared.
For instance active methods (such as querying patients) and use of check list are more likely to identify adverse effects than passive (relying on patient self report) or less focused methods. It is also important to consider how adverse effects are measured and if there are differences in measurements between studies (for example, for the adverse effect fever how and when the temperature is measured across trials should be taken into account).

Useful questions (also for observational studies), elaborated by the Cochrane Collaboration, to evaluate how adverse effects are collected are the following:

- Were definitions given of reported adverse effects?
- How were adverse effects data collected: prospective/routine monitoring, spontaneous reporting, patient checklist/questionnaire/diary; systematic survey of patients?

The quality of adverse effects reporting in RCTs is often variable. An evaluation of safety reporting in randomised trials across seven different medical areas demonstrated that safety reporting was often varying. Adverse effects were reported adequately only in 39% of the trials identified and many trials reported adverse effects without specifying severity and frequency.

The categorisation of adverse effects may differ across trials, making the synthesis of results difficult. Using a common, widely accepted scale would have the advantage that information can then be compared and synthesised across different studies. Standardised scales are available for some conditions, including the National Cancer Institute (Common Terminology Criteria for Adverse Event) and WHO scales. The CTCAE is considered the standard for reporting the severity of adverse effects in oncology clinical trials.

For these reasons HTA assessors should adequately evaluate how adverse effects are reported. The Cochrane Collaboration identified questions to assess the quality of reporting (also valid for observational studies):

- Were any patients excluded from the adverse effects analysis?
- Did the report give numerical data by intervention group?
- Which categories of adverse effects did investigators report?
- Did investigators report on all important or serious adverse effects, and how were these defined?
- Were the methods used for monitoring adverse effects reported?
- Was an independent data safety monitoring board established?

If adverse effects are independently adjudicated and/or confirmed by chart review, they should be evaluated.

The Consolidated Standards of Reporting Clinical Trials (CONSORT) presented the most frequent inadequate practices in reporting adverse effects in RCTs (see table 1) which should be considered when assessing data to include in the analysis.
Table 1. Practices to avoid in reporting adverse effects in RCTs (Ioannidis JP et al. 2004)

1. Using generic or vague statements, such as “the drug was generally well tolerated” or “the comparator drug was relatively poorly tolerated.”
2. Failing to provide separate data for each study arm.
3. Providing summed numbers for all adverse events for each study arm, without separate data for each type of adverse event.
4. Providing summed numbers for a specific type of adverse event, regardless of severity or seriousness.
5. Reporting only the adverse events observed at a certain frequency or rate threshold (for example, >3% or >10% of participants).
6. Reporting only the adverse events that reach a $P$ value threshold in the comparison of the randomised arms (for example, $P <0.05$).
7. Reporting measures of central tendency (for example, means or medians) for continuous variables without any information on extreme values.
8. Improperly handling or disregarding the relative timing of the events, when timing is an important determinant of the adverse event in question.
9. Not distinguishing between patients with 1 adverse event and participants with multiple adverse events.
10. Providing statements about whether data were statistically significant without giving the exact counts of events.
11. Not providing data on harms for all randomly assigned participants.

Although withdrawals are an important outcome, HTA assessors should be cautious when interpreting withdrawals as surrogates for safety or tolerability because of the potential for bias.

2.4.3 Observational studies

Because of the lack of randomisation the quality of observational studies should be adequately assessed.

Available instruments for evaluating observational studies vary in scope, number and types of items used and developmental rigor.\(^2\)

The STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) is a guidance on how to properly report observational studies and provides a checklist of 22 items that should be addressed in papers reporting cohort, case-control, and cross-sectional studies (see Annex 1. The STROBE statement - checklist of items that should be addressed in reports of observational studies).\(^4\)

Moreover, the Newcastle-Ottawa scale was developed to assess the quality of non randomised studies in meta-analysis. A study is judged according to three aspects: the selection of the study groups; the comparability of the groups; and the ascertainment of either the exposure or outcome of interest for case-control or cohort studies, respectively.\(^4\)

Additional factor to be considered can be: a) any validation of the case definition and/or outcomes (or absence of outcome) in the data source - either as part of the ongoing study or from literature. b) justification of the suitability of the proposed case/outcome definition for the safety study.

It is necessary to assess the quality of data on adverse reactions in observational studies. Most of the considerations presented for RCTs are valid and helpful also for observational studies.

2.4.4 Case reports

Given the considerable limitations HTA assessors should adequately assess published case reports when judging about their inclusion.

For this purpose the HTA assessors should consider the following aspects: \(^7\)

- Do reports have a good predictive value?
- Is there a causal relation between the intervention and the adverse event?
- Is there a plausible biological mechanism linking the intervention to the adverse events?
- Do reports provide enough information to allow detailed appraisal of the evidence?
- Are there any potential problems from using data from the reports, which might outweigh the perceived benefit of being comprehensive?

A set of desirable contents of a case report was proposed and included 14 items that are applied by the former Committee on Safety of Medicines’ yellow card in the United Kingdom, and 14 from the MedWatch adverse event forms in the United States (see Annex 2. Preferred contents of a case report).42

HTA assessors should take into account that published case reports and spontaneous reporting may provide different frequencies of adverse effects from those obtained from a meta-analysis of double-blind, randomised controlled trials.1

2.5 Synthesis and reporting of results by HTA assessors

At this stage of the assessment, after collecting the evidence and judging on their inclusion, HTA assessors should clearly describe included sources of information, risk of bias and quality of adverse reactions data, quantify adverse reactions in terms of frequency, incidence, severity and seriousness in comparison with its comparators.

2.5.1 Description of included sources of information

Characteristics of selected studies which may influence results and their external validity should be reported and summarised in table.43

Different approaches are available, including PRISMA Statement (Preferred reporting for Systematic Reviews and Meta-Analyses) and Cochrane Collaboration’s approach.44,45

PRISMA Statement recommends describing the characteristics of included studies (e.g. study size, follow-up period, PICOS). The Cochrane collaboration suggests to present a table entitled “Characteristics of included studies” including the following items: methods (study design, duration of the study); participants (setting, relevant details of health status of participants, age, sex and country); intervention (for pharmaceuticals, the name, dose, frequency, way of administration, duration); outcome and notes. Both approaches recommend describing the risk of bias of each study in a separate table.

According to these schemes useful information to be reported by HTA assessors are the following: methods (study design and follow-up period); characteristics of participants for both arms (setting, age, sex and country/geographic area, if appropriate race), intervention and comparator(s) (for pharmaceuticals: the name, dose, frequency, route of administration, duration), and outcomes. It is important to consider and to report the exposure of patients to the treatment. Methods used to collect adverse effects should be described as well (see table 2. as an example).

Tables describing characteristics of included studies can be presented separately for each study design as reported by Singh et al.46

2.5.2 Quantification of adverse effects in terms of frequency, incidence, severity and seriousness

According to previously developed guidelines (see Annex 3. Methods for documentation and selection criteria), results of individual studies can be presented by study arm in tabular form, using at least the following measures:
- Number of participants per study arm
- Number of patients excluded from the analysis dataset
- Patient-years of exposure
- Number of participants with the event
- Number of events
- Absolute risk; incidence rate (95% CI)
- Relative risk (95% CI)
- The quality of the evidence (e.g. high, moderate, low and very low)

If the adverse effects data is from an observational study, the relative risk estimate should be adjusted for potential confounding/effect modifying factors. Different tables can be elaborated for RCTs and observational studies.

The adverse effects should be grouped according to the System Organ Class (SOC). (The classification is available at: http://www.meddramsso.com).

The adverse effects which are common and serious should be reported separately. An example of reporting adverse effects is given in tables 3 adapted from NICE.

The description of adverse effects in terms of duration and reversibility is advisable to understand their burden, taking also into account the exposure to treatment.

Some authors proposed to use composite safety endpoints, merging in a single endpoint different types of adverse effects. As an example composite cardiovascular safety endpoint may include myocardial infarction and heart failure, stroke, coronary revascularisation and out-of-hospital cardiac death. The data must be provided for composite and single effects. The data can be given as either number of effects or hazard ratio (see tables 4 as an example). The use of composite endpoints can have the advantage to facilitate understanding of comparative safety data and to increase the statistical power because of the larger number of participants.

Adverse effects should also be provided by severity grade, for anticancer medicines according to the Common Terminology Criteria for Adverse Events (CTCAE) Version 4.0, which includes 5 grades of severity (mild, moderate, severe, life-threatening and death) differently from the previous versions including 4 grades. The EPAR may report the data according to the former versions. An example of reporting adverse effects for anticancer medicines is given in table 5. The effects are reported by frequency: Very common (≥1/10), Common (≥1/100 and <1/10), Uncommon (≥1/1000 and <1/100), Rare (≥1/10,000 and <1/1000), Very rare (<1/10,000) and not known.

Source: EMA. EPAR (pemetrexed)

Differences in adverse effects among population subgroups (e.g. elderly, adults and children) and specific safety concerns should be addressed and discussed. Adverse effects from different study designs cannot be pooled together using standard meta-analysis principles. Further, the data from non-randomised studies are more prone to bias and they are often heterogeneous; they should not be combined if there is important heterogeneity. Therefore in these circumstances adverse effects data is best summarised in a qualitative or in a descriptive manner.¹

2.5.3 Comparison of the safety profile of the pharmaceutical to the comparator(s)

At this stage HTA assessors should describe the safety profile of the pharmaceutical in comparison to the comparator(s), with special regard to the serious and most frequent adverse reactions. They should evaluate if differences identified in adverse reactions between the products are clinically relevant. The evaluation of the clinical relevance should be performed taking into account the condition for which the treatment is used and the co-morbidities of the population. For instance, in chronic diseases also no serious adverse reactions may have important implications, as they may impair the adherence to the treatment. HTA assessors should describe limitations of the evidence and analyse how these limitations may affect estimates of the adverse reactions.²

The heterogeneity of the studies should be explored; differences in the characteristics of the studies may lead to different results. Possible effects of individual study characteristics (e.g. follow up period, methods used to identify adverse effects, study design, study size, characteristics of populations, severity of disease and funding sources) and the external validity of results should be studied and discussed in the interpretation of findings.¹¹
2.5.4 Balanced discussion of benefits and adverse effects

The assessment of relative safety together with relative benefits will contribute to establish a balanced assessment of the intervention compared to its comparator(s). Some frameworks reporting both benefits and adverse effects were proposed.\textsuperscript{50}

While performing REA, HTA assessors should describe possible consequences of safety appraisal on coverage decisions:
- coverage restriction: patients with high risk of developing a serious adverse effect may be excluded from a coverage
- reimbursement may be lower, restricted or not acceptable for pharmaceuticals with safety concerns

3. Discussion and Conclusions

Although there is no doubt on the importance of the relative safety assessment of pharmaceuticals, significant methodological issues still persist.

The identification of adverse reactions to include in the assessment can be challenging; unlike benefits which are well identified, some adverse reactions associated with a pharmaceutical intervention may not be identified in advance.\textsuperscript{7}

Moreover the identification of studies with data on adverse reactions is not necessarily straightforward for several reasons: some studies don’t collect and provide data on the frequency of adverse reactions and, even when adverse reactions are evaluated, the information is not reported in the title and abstract; in some cases papers are not assigned indexing terms for adverse reactions, even though they contain data on adverse reactions frequency, making difficult the identification of the study.\textsuperscript{17}

Clinical trials are usually powered to detect statistical significance of possible benefits of a pharmaceutical and only secondly designed to study safety.\textsuperscript{14} As a result the evidence on adverse reactions generated by RCTs may be inconclusive.\textsuperscript{2} Depending on the size and duration, clinical trials may fail in capturing long term and uncommon adverse reactions; in order to identify uncommon adverse reactions they should enrol a larger number of participants impacting negatively on time needed for development of the pharmaceutical.\textsuperscript{14}

In spite of these limitations the relative safety assessment plays an important role in the relative effectiveness assessment. The assessment of relative safety together with benefits contribute to establish a balanced assessment of the intervention and of its therapeutic value and to support the payers in making informed decisions on the coverage of the pharmaceutical.

For these reasons it is important to assess adverse reactions and benefits with the same methodological rigour and accuracy. It will be important to consider the rules laid down by the new pharmacovigilance legislation (Regulation (EU) No 1235/2010 Directive 2010/84/EU) and their implications for the safety assessment in the field of Relative Effectiveness Assessment. In this regard, HTA can take advantage of the input of the continuous benefit risk assessments to be performed by regulatory authorities.

When conducting relative safety assessment the objective of HTA assessors should be first to identify adverse reactions, then to examine data in terms of frequency, incidence, severity and seriousness and finally to compare the safety profile of the pharmaceutical with its comparator(s).

To ensure the use of appropriate terminology the MedDRA dictionary could be a useful tool. In rapid assessment primary sources of information are EPAR, SPC, RMP (when available), manufacturer dossier and published and unpublished (where acceptable under the specific HTA system guidelines) clinical trials. Other sources of information such as observational studies, registries and confirmed relevant signals are also useful when available.

As the quality of primary data on adverse reactions may be heterogeneous, it is important to evaluate, apart from the risk of bias, how adverse effects were collected and reported in the studies.

Main characteristics of sources information should be reported and summarised in tabular form. Results on adverse reactions, categorised by SOC, should be reported in terms number of participants per study arm, number of patients excluded from the analysis dataset, patient-years of
exposure, number of events, number of participants with the event, absolute risk, incidence rate, relative risk and the quality of evidence for the pharmaceuticals and the comparator(s). Finally a description of the safety profile of the pharmaceutical in comparison with its comparator(s) with special regard to the most frequent, serious and severe adverse reactions should be given. External validity and heterogeneity of included sources of information, considering all factors which may influence the occurrence of adverse reactions (follow up period, methods used to identify adverse effects, study design, study size and characteristics of the population included), should be taken into account in the interpretation of findings.
Annexe 1: The STROBE statement

Checklist of items that should be addressed in reports of observational studies

<table>
<thead>
<tr>
<th>Item number</th>
<th>Recommendation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Title and abstract</td>
<td>(a) Indicate the study’s design with a commonly used term in the title or the abstract. (b) Provide in the abstract, an informative and balanced summary of what was done and what was found.</td>
</tr>
<tr>
<td>Introduction</td>
<td>Explain the scientific background and rationale for the investigation being reported</td>
</tr>
<tr>
<td>Methods</td>
<td>State specific objectives, including any prespecified hypotheses</td>
</tr>
<tr>
<td>Study design</td>
<td>Present key elements of study design early in the paper</td>
</tr>
<tr>
<td>Setting</td>
<td>Describe the setting, locations, and relevant dates, including periods of recruitment, exposure, follow-up, and data collection</td>
</tr>
<tr>
<td>Participants</td>
<td>(a) Cohort study—Give the eligibility criteria, and the sources and methods of selection of participants. Describe methods of follow up. Case-control study—Give the eligibility criteria, and the sources and methods of case ascertainment and control selection. Give the rationale for the choice of cases and controls. Cross-sectional study—Give the eligibility criteria, and the sources and methods of selection of participants. (b) Case-control study—For matched studies, give matching criteria and number of exposed and unexposed. Case-control study—For matched studies, give matching criteria and the number of controls per case.</td>
</tr>
<tr>
<td>Variables</td>
<td>Clearly define all outcomes, exposures, predictors, potential confounders, and effect modifiers. Give diagnostic criteria, if applicable</td>
</tr>
<tr>
<td>Data sources/measurement</td>
<td>For each variable of interest, give sources of data and details of methods of assessment (measurement). Describe comparability of assessment methods if there is more than one group.</td>
</tr>
<tr>
<td>Bias</td>
<td>Describe any efforts to address potential sources of bias</td>
</tr>
<tr>
<td>Study size</td>
<td>Explain how the study size was arrived at</td>
</tr>
<tr>
<td>Quantitative variables</td>
<td>Explain how quantitative variables were handled in the analyses. If applicable, describe which groupings were chosen, and why</td>
</tr>
<tr>
<td>Statistical methods</td>
<td>(a) Describe all statistical methods, including those used to control for confounding. (b) Describe any methods used to examine subgroups and interactions. (c) Explain how missing data were addressed. (d) Cohort study—If applicable, explain how loss to follow up was addressed. Case-control study—If applicable, explain how matching of cases and controls was addressed. Cross-sectional study—If applicable, describe analytical methods taking account of sampling strategy. (e) Describe any sensitivity analyses.</td>
</tr>
<tr>
<td>Results</td>
<td>(a) Report the numbers of individuals at each stage of the study—e.g., numbers potentially eligible, examined for eligibility, confirmed eligible, included in the study, completing follow up, and analyzed. (b) Give reasons for nonparticipation at each stage. (c) Consider use of a flow diagram. (a) Give characteristics of study participants (e.g., demographic, clinical, social) and information on exposures and potential confounders. (b) Indicate the number of participants with missing data for each variable of interest. (c) Cohort study—Summarize follow-up time (e.g., average and total amount).</td>
</tr>
<tr>
<td>Outcome data</td>
<td>Case-control study—Report numbers of outcome events or summary measures over time. Case-control study—Report numbers in each exposure category, or summary measures of exposure. Cross-sectional study—Report numbers of outcome events or summary measures.</td>
</tr>
<tr>
<td>Main results</td>
<td>(a) Give unadjusted estimates and, if applicable, confounder-adjusted estimates and their precision (e.g., 95% confidence interval). Make clear which confounders were adjusted for and why they were included. (b) Report category boundaries when continuous variables were categorized. (c) If relevant, consider translating estimates of relative risk into absolute risk for a meaningful time period.</td>
</tr>
<tr>
<td>Other analyses</td>
<td>Report other analyses done—e.g., analyses of subgroups and interactions, and sensitivity analyses.</td>
</tr>
<tr>
<td>Discussion</td>
<td>Key results</td>

**Guidelines, reports, recommendations already available**
A review of the guidelines used by HTA agencies addressing the assessment of safety and the methods to report data on adverse events was conducted and the following documents were selected:

EUnetHTA – European network for Health Technology Assessment
The most common practices used to report the safety data in a HTA report were identified. The results of the review are shown in table 6.

Table 6. Methods to report safety data by EMA, FDA, Cochrane and by the HTA agencies

**Other**

Bibliography of selected documents

**Bibliographic search strategy**

EUnetHTA – European network for Health Technology Assessment
The sources of information were searched for the period 2000-2010. The search was restricted to human subjects and to English language.

**Selection criteria**

Documents were selected for this review if they addressed the methodological issues related to the assessment of relative safety conducted by HTA assessors; documents related only to relative effectiveness and concerning issues of regulatory competence were excluded. The selection of the papers was carried out in two phases. A first screening was conducted in according to the title and abstract, afterwards the full texts of the papers selected relevant to the guidance were identified.

**Figure 1. Flow chart diagram of study selection**

Research in medline:
Adverse drug reaction or (adverse event and drug therapy) or (adverse effect and drug therapy) or comparative effectiveness or comparative effectiveness research or drug safety or comparative safety.

**Titles and abstracts identified and screened n = 4772**

Not available and excluded because clearly not relevant for the scope of the guideline n=4535

Full copies retrieved and assessed for eligibility n= 237

Excluded because
- Discussing only relative effectiveness
- Not discussing methodological issues concerning relative safety of interest of HTA assessors n= 211

Documents identified from reference list and web sites n=29

Publications meeting inclusion criteria n=55
